

LLM Bot

Function

The **LLM Bot** object can be used to send caller or IVR input to a configured **Chat Connector** chatbot or RAG endpoint.

The object simplifies chatbot integration in voicebot routing applications by providing a dedicated configuration instead of requiring manual low-level REST API request handling.

Parameters

Chat Connectors	Specifies the configured Chat Connector which should process the request. The selected Chat Connector provides the chatbot or RAG endpoint configuration.
Sender	Identifies the sender of the request. The value can contain variables from the routing application as required.
Message	The text which is sent to the selected Chat Connector. The message can contain caller input, IVR-generated content or variables available within the routing application.
Timeout	Specifies how long the routing application waits for the Chat Connector request to complete.
Variable Prefix Result	Specifies the prefix used for the result variables returned by the object. This allows the returned data to be stored using a defined variable prefix and referenced by subsequent objects in the routing application.

Outputs

Output	Used when ...
OK	The request was executed successfully.
Other	The request completed, but returned a non-success response.

Error	The request could not be executed or a technical error occurred.
